We will review *analytic and numerical techniques* for solving ODEs, using pencil and paper, and implemented in Matlab. These simple techniques lay the foundations for solving more complex systems of PDEs in the coming weeks.

By way of example we study the dynamics of a *ring oscillator*, a circular chain of three inverters with identical capacitive loading.

$$\begin{aligned}
 C \frac{dv_1}{dt} &= g(v_3) \approx -G v_3 & v_1(0) &= v_{10} \\
 C \frac{dv_2}{dt} &= g(v_1) \approx -G v_1 & v_2(0) &= v_{20} \quad (4) \\
 C \frac{dv_3}{dt} &= g(v_2) \approx -G v_2 & v_3(0) &= v_{30}
 \end{aligned}$$

# Eigenvalues

Ring oscillator ODE dynamics in matrix notation:

$$\frac{d\mathbf{v}}{dt} = \mathbf{A}\mathbf{v} \quad \mathbf{v}(0) = \mathbf{v}_0 \quad (5)$$

with

$$\mathbf{v} = \begin{pmatrix} v_1 \\ v_2 \\ v_3 \end{pmatrix} \quad \mathbf{A} = \begin{pmatrix} 0 & 0 & -1 \\ -1 & 0 & 0 \\ 0 & -1 & 0 \end{pmatrix} \quad \mathbf{v}(0) = \begin{pmatrix} v_{10} \\ v_{20} \\ v_{30} \end{pmatrix} \quad (6)$$

where  $G/C \equiv 1$  with no loss of generality.

Eigenvectors  $\mathbf{x}_i$  and corresponding eigenvalues  $\lambda_i$  of  $\mathbf{A}$  satisfy  $\mathbf{A} \mathbf{x}_i = \lambda_i \mathbf{x}_i$ , or  $\det(\mathbf{A} - \lambda_i \mathbf{I}) = 0$ , which reduces to  $\lambda_i^3 + 1 = 0$ , with three solutions:

$$\lambda_i = (-1)^{\frac{1}{3}} = \begin{cases} -1 \\ e^{+j\pi/3} = \frac{1}{2} + j\frac{\sqrt{3}}{2} \\ e^{-j\pi/3} = \frac{1}{2} - j\frac{\sqrt{3}}{2} \end{cases}$$

## Eigenvectors

Overview

Example: Ring  
Oscillator  
DynamicsAnalytic ODE  
SolutionNumerical  
VerificationNumerical  
Simulation

Further Reading

The corresponding eigenvectors are:

$$\begin{aligned}
 \lambda_1 &= -1 : & \mathbf{x}_1 &= \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \\
 \lambda_2 &= e^{+j\pi/3} = \frac{1}{2} + j\frac{\sqrt{3}}{2} : & \mathbf{x}_2 &= \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ e^{+j2\pi/3} \\ e^{-j2\pi/3} \end{pmatrix} \\
 \lambda_3 &= e^{-j\pi/3} = \frac{1}{2} - j\frac{\sqrt{3}}{2} : & \mathbf{x}_3 &= \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ e^{-j2\pi/3} \\ e^{+j2\pi/3} \end{pmatrix}
 \end{aligned} \tag{8}$$

The eigenvectors form a complex orthonormal basis:

$$\mathbf{x}_i^* \mathbf{x}_j = \delta_{ij}, \quad i, j = 1, \dots, 3 \tag{9}$$

where  $\mathbf{x}_i^*$  is the complex conjugate transpose of  $\mathbf{x}_i$ .

# Eigenmodes

The general solution is the superposition of eigenmodes (see Lecture 1):

$$\begin{aligned}
 \mathbf{v} &= \sum_{i=1}^3 c_i \mathbf{x}_i e^{\lambda_i t} \\
 &= c_1 e^{-t} \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} + \\
 &\quad c_2 e^{\frac{1}{2}t} e^{j\frac{\sqrt{3}}{2}t} \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ e^{+j2\pi/3} \\ e^{-j2\pi/3} \end{pmatrix} + \\
 &\quad c_3 e^{\frac{1}{2}t} e^{-j\frac{\sqrt{3}}{2}t} \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ e^{-j2\pi/3} \\ e^{+j2\pi/3} \end{pmatrix}
 \end{aligned} \tag{10}$$

$\mathbf{v}(t)$  is real, and so  $c_2$  and  $c_3$  must be complex conjugate.

Therefore, the second and third eigenmodes are oscillatory with an exponentially rising carrier. The first eigenmode is a decaying exponential common-mode transient.

# First Eigenmode– Common-mode Decaying Exponential

**Figure:** Ring oscillator ODE solution for  $\mathbf{v}(0) = (1, 1, 1)^T$ .

**Figure:** Ring oscillator ODE solution for  $\mathbf{v}(0) = (1, -\frac{1}{2}, -\frac{1}{2})^T$ .

## Initial Conditions

The IC constrained solution is obtained by virtue of the orthonormality of the eigenvectors (see also Lecture 1):

$$\mathbf{v} = \sum_{i=1}^n \mathbf{x}_i^* \mathbf{v}(0) \mathbf{x}_i e^{\lambda_i t} \quad (11)$$

which, using the identity  $e^{+j\alpha} + e^{-j\alpha} = 2 \cos(\alpha)$ , leads to:

$$\begin{aligned} v_1 = & \frac{e^{-t}}{3} (v_{10} + v_{20} + v_{30}) + \\ & \frac{2 e^{t/2}}{3} (v_{10} \cos(\frac{\sqrt{3}}{2} t) + \\ & v_{20} \cos(\frac{\sqrt{3}}{2} t + \frac{2\pi}{3}) + v_{30} \cos(\frac{\sqrt{3}}{2} t - \frac{2\pi}{3})) \end{aligned} \quad (12)$$

and identical expressions for  $v_2$  and  $v_3$  under ordered permutation of the indices (consistent with the ring symmetry).

## Matlab Implementation

Overview

Example: Ring  
Oscillator  
DynamicsAnalytic ODE  
SolutionNumerical  
VerificationNumerical  
Simulation

Further Reading

Using the eigenvector-eigenvalue decomposition of  $\mathbf{A}$  in matrix form:

$$\mathbf{A} \mathbf{X} = \mathbf{X} \mathbf{s} \quad (13)$$

where  $\mathbf{X} = (\mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_3)$  and  $\mathbf{s} = \text{diag}(\lambda_1, \lambda_2, \lambda_3)$ , the solution (11) can be expressed in matrix form:

$$\mathbf{v} = \mathbf{X} \text{diag}(\mathbf{X}^* \mathbf{v}(0)) e^{\text{diag}(\mathbf{s})t} \quad (14)$$

for efficient matlab implementation:

```
[X, s] = eig(A);  
V = X * diag(X' * V0) * exp(diag(s) * t);
```

# Initial Conditions

**Figure:** Ring oscillator ODE solution for  $\mathbf{v}(0) = (1, 0, 0)^T$ .

# Euler Integration

Euler numerical integration produces approximate solutions to:

$$\frac{d\mathbf{x}}{dt} = \mathbf{f}(\mathbf{x}(t), t) \quad (15)$$

at discrete time intervals  $t = n\Delta t$ , by finite difference approximation of the derivative:

$$\frac{d\mathbf{x}}{dt}(t) = \frac{1}{\Delta t}(\mathbf{x}(t + \Delta t) - \mathbf{x}(t)) + \mathcal{O}(\Delta t^2) \quad (16)$$

leading to the recursion:

$$\mathbf{x}(t + \Delta t) \approx \mathbf{x}(t) + \Delta t \mathbf{f}(\mathbf{x}(t), t). \quad (17)$$

Matlab *Euler* example (ring oscillator):

```

Ve = V0; % Euler approximation, initialize to IC
Vs = V0; % Euler state variable, initialize
for te = tstep:tstep:trange
    Vs = Vs + A * Vs * tstep;
    Ve = [Ve, Vs];
end

```

## Crank-Nicolson Integration

Better numerical ODE methods exist that use higher-order finite difference approximations of the derivative. *Crank-Nicolson* is a second order method that approximates (15) more accurately using a centered version of the finite difference approximation of the derivative:

$$\frac{d\mathbf{x}}{dt}\left(t + \frac{\Delta t}{2}\right) = \frac{1}{\Delta t}(\mathbf{x}(t + \Delta t) - \mathbf{x}(t)) + \mathcal{O}(\Delta t^3) \quad (18)$$

leading to a recursion:

$$\begin{aligned} \mathbf{x}(t + \Delta t) &\approx \mathbf{x}(t) + \Delta t \mathbf{f}\left(\mathbf{x}\left(t + \frac{\Delta t}{2}\right), t + \frac{\Delta t}{2}\right) \\ &\approx \mathbf{x}(t) + \frac{\Delta t}{2}(\mathbf{f}(\mathbf{x}(t), t) + \mathbf{f}(\mathbf{x}(t + \Delta t), t + \Delta t)) \end{aligned} \quad (19)$$

Matlab *CN* example (ring oscillator):

```
G = (eye(3) - A * tstep / 2) \ (eye(3) + A * tstep / 2);
Vc = V0; % CN approximation, initialize to IC
Vs = V0; % CN state variable, initialize
for te = tstep:tstep:trange
    Vs = G * Vs;
    Vc = [Vc, Vs];
end
```

Further Reading

Crank-Nicolson (19) is *implicit* in that the solution at time step  $t + \Delta t$  is recursive in the state variable  $\mathbf{x}(t + \Delta t)$ , rather than forward *e.g.*, given in previous values of the state variable  $\mathbf{x}(t)$ . More advanced methods, such as *Runge-Kutta* and several of Matlab's built-in ODE solvers, are explicit and/or higher order, allowing faster integration although possibly at the expense of numerical stability.

Matlab *ode23* example (ring oscillator):

```
OdeOptions = odeset('RelTol', 1e-9); % accuracy, please  
dVdt = @(t,V) A * V;  
[tm, Vm] = ode23(dVdt, [0 trange], V0);
```
